

TRENDS IN WORLD GRAIN PRODUCTION

1960 TO 1972

Area • Production • Yield

FOREWORD

Developments in the world grain economy in the 1972-73 season have brought renewed worldwide attention to food supply conditions and the influence of weather variations. World grain production dropped in 1972, and while much of this was due to an extraordinary decline in Russian grain production, there have also been significant interruptions of upward trends in grain output in other areas of the world.

Among the questions most commonly raised in the wake of recent world grain supply developments are (1) whether the so-called green revolution begun in the late 1960's is slowing down, (2) whether unusual extremes of weather are the sole explanation for this past year's crop downturn, and (3) whether the rate of long-term growth in world grain output may be changing.

This report presents and analyzes some of the essential data relating to such questions. Graphic illustrations and a variety of country groupings are used to summarize what appear to be the most significant aspects of year-to-year development of world grain production patterns over the past 13 years. Analysis has focused mainly on the broad impressions derived from study of the graphic presentations and the summary tables showing aggregates for country groupings.

Data on rice production are not included in this report; these appeared in another recent report, FAS-M-246, August 1972. Current-year world production estimates, showing complete country-by-country detail, are regularly published three times each year for wheat, rye, and corn, and twice yearly for barley, oats, and rice in the grain series of Foreign Agriculture circulars. This information is also found in the monthly *World Agricultural Production and Trade: Statistical Report*. In addition, a Special Supplement to the World Agricultural Situation, concentrating upon the world grain situation, was published jointly by the Economic Research Service and the Foreign Agricultural Service in October 1972; the main estimates contained in that report have since been updated twice through Foreign Agriculture Grain Circulars FG 15-72 and FG 1-73.

LONG-TERM TRENDS AND PATTERNS OF WORLD GRAIN PRODUCTION¹

World grain output has been rising at a rate of roughly 2 percent annually over the 13-year period reviewed in this report. The total volume of world output of all grains, including wheat, rye, corn, barley, oats, and grain sorghum, is currently about 830 million metric tons. The wheat portion of total world grain output has been increasing slightly, and currently is about two-fifths.

For aggregate world grain output, year-to-year fluctuations are relatively small, normally within a range of less than 5 percent above or below the long-term trend. This suggests that in most years there is a tendency for bumper crop outturns occurring in some areas of the world to be offset by relatively poor crops in other geographic areas. This pattern may be changing somewhat, however, in that abnormally wide deviations from trend have occurred in 2 of the past 3 years.

Relative to the volume of output, there is larger yearly fluctuation in world production of wheat than of coarse grains. Although world coarse grain output is about 70 percent greater than wheat output, variations in wheat production make up well over half of the yearly fluctuation in world output of total grains.

Relative Importance of Area and Yield

During the years covered by this report, yield has been by far the most important factor in explaining long-term developments in world grain output. Area has risen only about 2 percent over the 13-year period while yield has risen by about 40 percent.

The trend in area is somewhat obscured by the fact that major programs for temporary retirement of grain cropland have been in effect in the United States throughout the entire period. Under the influence of these programs, grain area in the United States—approximately one-eighth of the World total—has trended generally downward; this is contrary to the trend for most other areas of the world. The operation of cropland retirement programs in the United States has involved some rather wide year-to-year adjustments over the period under review, and

these have also obscured the general pattern of worldwide grain area trends.

When the United States is excluded, the total grain area of all foreign countries showed a small increase in the early 1960's. This has since appeared to level off. Within the "all foreign" segment, much of the change in area in recent years is in Australia, Argentina, and Canada. These countries experienced significant overall expansion of cropland area during the period of 1960 to 1968 and in all cases there has been a slight dropoff in recent years; in Canada, grain area was curtailed sharply in 1970 by 1-year program aimed at bringing grain production into line with demand.

So far as yield is concerned, the rate of annual increase in the United States is somewhat larger than that of the total of all foreign areas. Grain yield in the United States appears to have risen at an annual rate of almost 4 percent in the period under review, and the aggregate yield for all foreign areas appears to have risen about 2.5 percent.

So far as absolute yield levels are concerned, grain yields in the United States continue to be well above the average for the rest of the world. For the aggregate of total grains, recognizing that factors such as proportions of individual grains and the percentage of irrigated area have an important bearing, the average yield for the United States is currently more than double that for the rest of the world.

Unusually sharp deviations from the world long-term yield trends occurred in both 1970 and 1972. A sharply lower yield in 1970 was mainly due to the impact of corn blight in the United States. The drop experienced in 1972 was due to lower yields in foreign countries and was the sharpest reduction that had occurred during the entire period under review.

There are also some significant differences between wheat and other grains in the relative importance of area and yield. For example, whereas overall yield increases have been slightly more rapid for the United States than for the aggregate of all foreign countries, in the case of wheat, yield increase has been slightly lower for the United States than that for all foreign countries. Thus, in the coarse grains sector,

¹ Statistical presentations and analysis for this report were prepared by Ansel S. Wood, Agricultural Economist, Commodity Analysis Branch, Grain Division, FAS.

overall foreign yields have tended to lag behind those of the United States; detailed review shows, moreover, that most of this lag is due to sharp increases in United States corn yields.

Corn weighs heavily in the aggregate United States yield, since corn accounts for about four-fifths of total United States coarse grain output and almost two-thirds of total United States output of all grains. In foreign countries, corn accounts for only about two-fifths of total coarse grain output and, with the exception of parts of Western Europe, corn yield increases have generally been (1) far less rapid than in the United States, and (2) not significantly greater than yield increases for other grains.

Another significant contrast between coarse grains and wheat is that, among foreign countries, coarse grain area has tended to move quite consistently upward, and with very slight year-to-year changes, whereas wheat area has shown considerable irregularity. Despite the gradual increase in coarse grain area among foreign countries, the relatively low rate of yield growth for coarse grains compared with wheat has tended to give wheat a slightly increasing share of total foreign grain output over the period under review.

Comparison of Yields—Levels and Growth Rates

Review of wheat, barley, and corn yields for the 1960-1972 period indicates that one of the most striking features is the high level and relatively rapid growth of corn yields in both the United States and Western Europe. Another dominant feature is that yield increases for all of the grains appear to have been more rapid in the European Community than for other areas, including the United States. In fact, the United Kingdom and the European Community differ sharply in yield changes for both wheat and barley, possibly reflecting differences in levels of protection for domestic grain production, or changes in such protection, which evolved during the 1960-72 period.

Grain Production Changes Among Different Trade Groupings

By dividing the world into several broad segments according to grain trading position or significance, a number of additional observations can be made.

In the "major competing countries"—Argentina, Australia and Canada—wheat accounted for over 60 percent of total grain area during most of the 1960's. However, because of surplus world wheat stocks, the area in wheat declined sharply in 1969 and 1970 to a low of 44 percent. Among other major trading areas outside the United States, the wheat portion of total

grain output has been quite stable, but in the remainder of the world—mainly the less developed countries—the wheat proportion declined gradually from 1960 to 1966, and has since increased again rather steadily.

Within these country groupings, the largest volume of increase in total grain output during the period under review has been accounted for by the "other major trading areas"—Europe, USSR, Mainland China, and Japan. For Eastern Europe and the USSR, which make up slightly over half of the total of this grouping, grain output has risen by roughly one-third during the period under review. For Western Europe, which accounts for about one-third of the total for this group, grain production has risen by a similar margin, although a large portion of the increase has been confined to the six countries making up the original European Community. For Mainland China, the increase in total grain output appears to have been slightly less than that for Europe and the USSR, while grain output in Japan, has been declining steadily.

For the "major competing exporters" group, an increasing trend was evident for the approximate period 1960-66, but there has been no significant further expansion. There have been frequent shifts toward greater or lesser proportions of wheat as opposed to coarse grains throughout the past 13 years, but since 1966 the total volume of output for all grains has been generally unchanged. These three countries account for approximately 8 percent of total world grain output as compared with over one-fourth of the world total in the case of the United States.

The remaining group of countries, entitled "all other" on the accompanying graphic illustrations, which excludes the United States, the "major competing exporters", and the "other major trading areas", consists essentially of the countries of Africa, Latin America, and Asia. This group is of particular interest since it includes most of what are commonly referred to as the less developed countries. Total grain output in this group makes up about 20 percent of the world total. Expansion of output within this group has been due about equally to both area and yield increases.

For the 13-year period as a whole, output has increased by roughly the same proportion in this area as it has in the "major trading areas" group, but it may be significant that virtually all of this expansion occurred during the period 1960-68. Since 1968, there has been some leveling off in the trend, due mainly to a lack of further area increase. It is possible that some slow down in yield increases among this group of countries has also occurred, but this is not yet clearly evident.

NOTES TO CHARTS AND TABLES

1. Production years shown throughout this report refer to the year of harvest in the Northern Hemisphere. Harvests of Northern Hemisphere countries are combined with those of the Southern Hemisphere which immediately follow; thus the crop harvested in the Northern Hemisphere during the calendar year listed is actually combined with the Southern Hemisphere crop which is harvested either later in the same calendar year, or in the case of corn and sorghum, early in the following calendar year. This note is of particular importance because of the tendency for misunderstanding when alternatively referring to production years or marketing years. For example, the South African corn crop listed under the world production year 1971 is actually the crop harvested in May 1972 and marketed during the South African marketing year 1972/73.
2. All data for grain area represent harvested rather than planted area, wherever possible.
3. Data for "EC", i.e. European Community, represent totals for the original six member countries.
4. Data for the USSR are expressed in terms of estimated "storable" or "net grain" as opposed to the "gross weight" or "bunker weight" terms used in official Soviet statistics.
5. The basic source of data in this report is the latest official statistics released by the governments of the countries concerned. Other sources include reports of international organizations such as FAO, reports from United States Agricultural Attache offices, and information from trade reports and other unofficial sources.
6. Conversion factors which may be helpful with the data in this report are:
 - a. For harvested area: 1 hectare = 2.471 acres; 1 acre = 0.40469 hectare
 - b. For yield: 1 metric quintal per hectare = 1.4870 bushels per acre for wheat, 1.5932 bushels per acre for corn, rye or sorghum; 1.8587 bushels per acre for barley, and 2.7881 bushels per acre for oats
 - c. For total production: 1 metric ton = 36.7437 bushels for wheat, 39.368 bushels for corn, grain sorghum or rye; 45.9296 bushels for barley, and 68.8944 bushels for oats.
 - d. For converting U.S. domestic and metric weights: 1 metric ton = 2204.622 pounds; 1 metric ton = 1.102311 short tons; 1 metric ton = 0.984206 long tons

1/ Years shown refer to year of harvest in the Northern Hemisphere. Harvests of Northern Hemisphere countries are combined with those of the Southern Hemisphere which immediately follow; thus, the crop harvested in the Northern Hemisphere is combined with the Southern Hemisphere harvest which begins late in the year and ends early in the next year.

1/ Years shown refer to year of harvest in the Northern Hemisphere. Harvests of Northern Hemisphere countries are combined with those of the Southern Hemisphere which immediately follow; thus, the crop harvested in the Northern Hemisphere in combined with the Southern Hemisphere harvest which begins late in the year and ends early in the next year.

2/ EC data.

1/ Years shown refer to year of harvest in the Northern Hemisphere. Harvests of Northern Hemisphere countries are combined with those of the Southern Hemisphere which immediately follow; thus, the crop harvested in the Northern Hemisphere is combined with the Southern Hemisphere harvest which begins late in the year and ends early in the next year.

2/ EC data.
